Lesson 7: Searching and Updating Objects

Focus: Searching for objects and manipulating their attributes.

The school wants users to search for students using their admission numbers.

Exercise 7 – Adding Student Search Functionality

Modify the `Student` class by adding a new attribute:

`- admissionNumber`

Update the constructor to initialise the admission number.

Continue using the `students` collection from Lesson 6.

Questions

1. Modify the constructor to accept an admission number.
2. Add a method called `getAdmissionNumber()` that returns the student's admission number.
3. Write a function called `searchStudent(admissionNumber)` that searches through the collection of Student objects.
4. If a student is found, display their details.
5. If no student is found, display "Student not found".
6. Write a function called `updateStudentMarks(admissionNumber)` that searches for a student and allows their marks to be updated.
7. Write a function called `removeStudent(admissionNumber)` that removes a student from the collection.
8. Test the search, update and removal functions using different admission numbers.

Challenge question: Modify the search functionality so that users can also search for students using their names or surnames.

Learning checkpoint: Learners should understand how to locate a specific object within a collection and perform operations on it.
