LESSON 2: Functions with Parameters

Focus: Passing information into functions.

Objective: Understand how parameters allow one function to work with different values each time it is called.

A **parameter** is a variable listed in a function **definition**. An **argument** is the actual value supplied when the function is **called**.

```
Function CalculateSquare(ByVal number As Integer) As Integer
    Return number * number
End Function

Sub Main()
    Console.WriteLine(CalculateSquare(5))
    Console.WriteLine(CalculateSquare(8))
End Sub
```

Expected output: 25 and 64 (each on a separate line).

Exercise 5 – Greeting Function

Create a function called **`DisplayGreeting`**. It must accept a student's name as a parameter and return a greeting message containing that name. For example, passing "Peter" should return "Welcome to Computer Science, Peter!" Call the function using at least three different names.

Exercise 6 – Adding Two Numbers

Create a function called **`AddNumbers`**. It must accept two integer parameters, calculate their sum and return the answer. Test your function using the following values:

First number	Second number
10	20
45	15
100	250
75	125

Exercise 7 – Calculating the Difference

Create a function called **`SubtractNumbers`**. It must accept two numbers and return their difference. Test it using different values.

Exercise 8 – Multiplication Function

Create a function called **`MultiplyNumbers`**. It must accept two integer parameters, multiply them and return the result. Call the function five times using different values.

Exercise 9 – Division Function

Create a function called **`DivideNumbers`**. It must accept two numbers, divide the first number by the second, and return the answer as a Double. Check whether the second number is zero before dividing. For this exercise, return 0 if the divisor is zero.
